The identical reasoning holds at C ($dD \parallel CS$), at D, and at every vertex: each deflection lies parallel to the radius, so the impulse always aims at S. Taking the polygon to its limit, the radial force directions BS, CS, DS converge continuously on the centre — the force is centripetal. Thus the equal-area observation ALONE locks the direction toward S, however the magnitude may vary with distance; combined with Proposition I this makes swept area the definitive test of a central force. *Q.E.D.*
