The correspondence lines pair each strip of the upper figure with its mate below: p_1 with q_1, p_2 with q_2, p_3 with q_3. By hypothesis every such pair shares one ultimate ratio k, so that $p_i/q_i \to k$ each to each respectively. Then, by composition, the sum of all the upper parallelograms is to the sum of all the lower parallelograms in that same ratio k, since adding terms of equal ratio preserves the ratio. Finally, by Lemma III each rank of parallelograms is ultimately equal to its own curvilinear figure — so the sums may be replaced by the whole figures, giving $AacE : PprT = k$. Thus two figures whose corresponding strips share an ultimate ratio are themselves in that very ratio. *Q.E.D.*
