

Take the very figure of Lemma IX and give it a body and a clock. Along the base we lay off the times AD and AE — time runs horizontally, so a longer segment means a longer interval since the motion began at A . The curve ABC is now the growth of speed: a finite force (steady, or increasing, or slackening) urges the body, so at each instant it is moving faster than the last, exactly as Galileo saw in a falling stone. The upright ordinates DB and EC are the VELOCITIES reached at times AD and AE , drawn at a fixed angle to the base. Thus the flat geometric picture becomes a record of accelerated motion, with time below and speed above.
