

The change of motion is made in the direction of the right line in which the force is impressed. This motion, being always directed the same way with the generating force, if the body moved before, is added to or subducted from the former motion — according as they directly conspire with or are directly contrary to each other; or obliquely joined, when they are oblique, so as to produce a new motion compounded from the determination of both. Thus $\Delta(\text{motion})$ runs parallel to F .
