

The **change of motion** is made **in the direction of the right line** in which **the force** is impressed. This motion, being always directed the same way with **the generating force**, if the body moved before, is **added to or subducted from** the former motion — according as they directly conspire with or are directly contrary to each other; or **obliquely joined**, when they are oblique, so as to produce a new motion compounded from the determination of both. Thus $\Delta(\text{motion})$ runs **parallel** to **F**.
